

Simple Text Conversion Fixture - page 1

This document verifies plain body text extraction at real-world scale.

The pipeline must convert every paragraph to markdown without losing words

or inserting phantom symbols, and it must do so deterministically.

Sequential queue workers process files one by one so the memory footprint

returns to baseline after each item and allocation stays predictable.

Benchmarking measures character counts and latency for every document

in the suite, and the results are reported in a machine-readable phase

report that is verified by the delivery gate before completion.

Native Rust compilation is delegated to the GitHub Actions runner while

the local machine keeps a lightweight toolchain for scripts and tests.

Artifacts are verified for presence and size before a phase report may

be marked complete, and cache keys isolate test builds from releases.

The graphical shell follows Apple design guidelines with a fixed window

size, a deep dark theme, and minimalist status indicators.

Documents with mixed scripts, complex tables, and embedded images are

exercised so that regressions cannot hide behind toy-sized fixtures.

Encrypted files return a structured failure, and password-protected

content is never written to disk unless authentication succeeds.

Long-running conversions can be cancelled by the user at any moment and

the engine process is terminated promptly without leaking memory.

The watchdog deadline protects the queue from pathological documents

Simple Text Conversion Fixture - page 2

that would otherwise stall conversion for hours.

Paths containing spaces are handled correctly on Windows, including folders such as My Documents that are common in real deployments.

Every release artifact is a single lightweight installer that runs fully offline with no telemetry and no cloud dependency.
